# Deep Reinforcement Learning and Control <br> Learning Local models, TRPO, Imitating Optimal Controllers 

Katerina Fragkiadaki

## Last lecture

Iterative-Linear Quadratic Regulator for continuous control: We assumed:

- known dynamics model
- we could measure the reward (state x was fully observed, thus also the distance from a desired state $x^{*}$ )
and we showed a local optimization process that would achieve the desired task from a specific initial state x_0 using iterative linear approximations of dynamics and quadratic approximations for the cost.

Learning global dynamics models using Neural Networks as the function class

## This lecture

- Learning local dynamics models
- i-LQR with learn local models
- Trust region constraint for policy optimization: TRPO and i-LQR
- Learning general policies by imitating i-LQR local controllers
- DAGGER
- Guided policy search

## Next lecture

- Differentiable model-based reinforcement learning
- Recurrent networks and optimal control
- Back-propagate directly to the policy using temporal unfoldingdifferentiable dynamics- back propagate through discrete actions (stochastic sampling on the forward pass), or through continuous actions (re-paramertization trick)

## (Locally) Optimal Control

$$
\begin{aligned}
& \min _{u_{1}, \ldots, u_{T}} \sum_{t=1}^{T} c\left(x_{t}, u_{t}\right) \text { s.t. } x_{t}=f\left(x_{t-1}, u_{t-1}\right) \\
& \min _{u_{1}, \ldots, u_{T}} c\left(x_{1}, u_{1}\right)+c\left(f\left(x_{1}, u_{1}\right), u_{2}\right)+\cdots+c\left(f(f(\ldots) \ldots), u_{T}\right)
\end{aligned}
$$

Differentiate and optimize.
Need derivates: $\frac{d f}{d x_{t}}, \frac{d f}{d u_{t}}, \frac{d c}{d x_{t}}, \frac{d c}{d u_{t}}$
In case $f$ is linear and $c$ quadratic, then we can using dynamic programming and get optimal solution!-> i-LQR, MPC extensions

## If we knew the dynamics

$$
\begin{aligned}
& \min _{\mathbf{u}_{1}, \ldots, \mathbf{u}_{T}} \sum_{t=1}^{T} c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right) \text { s.t. } \mathbf{x}_{t}=f\left(\mathbf{x}_{t-1}, \mathbf{u}_{t-1}\right) \\
& \min _{\mathbf{u}_{1}, \ldots, \mathbf{u}_{T}} c\left(\mathbf{x}_{1}, \mathbf{u}_{1}\right)+c\left(f\left(\mathbf{x}_{1}, \mathbf{u}_{1}\right), \mathbf{u}_{2}\right)+\cdots+c\left(f(f(\ldots) \ldots), \mathbf{u}_{T}\right)
\end{aligned}
$$

Global dynamics model would do. But we saw they are hard to fit/get them to generalize.
But if you use i-LQR, in any case it is a local optimization method, around reference trajectories! You don't need dynamics everywhere (at each iteration), only around the reference trajectory: $\hat{x}_{t}, \hat{u}_{t}$ !
(Time varying) Local models of dynamics! Local linear approximations!

## Time varying linear dynamics

reference trajectory $\hat{x}_{t}, \hat{u}_{t}, t=1, \ldots, T$

## Time varying linear dynamics

$$
\begin{gathered}
f\left(x_{t}, u_{t}\right) \approx \mathbf{A}_{t} x_{t}+\mathbf{B}_{t} u_{t} \\
\mathbf{A}_{t}=\frac{d f}{d x_{t}} \quad \mathbf{B}_{t}=\frac{d f}{d u_{t}}
\end{gathered}
$$

reference trajectory $\hat{x}_{t}, \hat{u}_{t}, t=1, \ldots, T$
learn time varying linear dynamics: $\mathbf{A}_{t}, \mathbf{B}_{t}$

## Time varying linear dynamics

$$
\begin{gathered}
f\left(x_{t}, u_{t}\right) \approx \mathbf{A}_{t} x_{t}+\mathbf{B}_{t} u_{t} \\
\mathbf{A}_{t}=\frac{d f}{d x_{t}} \quad \mathbf{B}_{t}=\frac{d f}{d u_{t}}
\end{gathered}
$$

reference trajectory $\hat{x}_{t}, \hat{u}_{t}, t=1, \ldots, T$
learn time varying linear dynamics: $\mathbf{A}_{t}, \mathbf{B}_{t}$

How do I get the data to fit my linear dynamics at each time step? We execute the controller $u_{t}$ at state $x_{t}$ to explore how the world works in the vicinity of the reference trajectory!

Which controller?

## Which controller to collect samples with?

- We need a stochastic controller! Why?

## Which controller to collect samples with?

- We need a stochastic controller! Why?
- Here is a good guess: add some noise to the output of iLQR:

$$
p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)=\mathcal{N}\left(\mathbf{K}_{t}\left(\mathbf{x}_{t}-\hat{\mathbf{x}}_{t}\right)+\mathbf{k}_{t}+\hat{\mathbf{u}}_{t}, \Sigma_{t}\right)
$$

## Which controller to collect samples with?

- We need a stochastic controller! Why?
- Here is a good guess: add some noise to the output of iLQR:
$p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)=\mathcal{N}\left(\mathbf{K}_{t}\left(\mathbf{x}_{t}-\hat{\mathbf{x}}_{t}\right)+\mathbf{k}_{t}+\hat{\mathbf{u}}_{t}, \Sigma_{t}\right)$
- It turns out that setting $\Sigma_{t}=Q_{u_{t}, u_{t}}^{-1}$ solves the following maximum entropy control problem:

$$
\min \sum_{t=1}^{T} E_{\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right) \sim p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)-\mathcal{H}\left(p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right)\right]
$$

## Which controller to collect samples with?

- We need a stochastic controller! Why?
- Here is a good guess: add some noise to the output of iLQR:

$$
p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)=\mathcal{N}\left(\mathbf{K}_{t}\left(\mathbf{x}_{t}-\hat{\mathbf{x}}_{t}\right)+\mathbf{k}_{t}+\hat{\mathbf{u}}_{t}, \Sigma_{t}\right)
$$

- It turns out that setting $\Sigma_{t}=Q_{u_{t}, u_{t}}^{-1}$ solves the following maximum entropy control probiem:

$$
\min \sum_{t=1}^{T} E_{\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right) \sim p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)-\mathcal{H}\left(p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right)\right]
$$

- Remember, cost to go:

$$
Q\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)=\text { const }+\frac{1}{2}\left[\begin{array}{l}
\mathbf{x}_{t} \\
\mathbf{u}_{t}
\end{array}\right]^{T} \mathbf{Q}_{t}\left[\begin{array}{c}
\mathbf{x}_{t} \\
\mathbf{u}_{t}
\end{array}\right]+\left[\begin{array}{l}
\mathbf{x}_{t} \\
\mathbf{u}_{t}
\end{array}\right]^{T} \mathbf{q}_{t}
$$

- The above controller strikes the right balance between minimizing the cost and maximize exploration

## Which controller to collect samples with?

$$
\min \sum_{t=1}^{T} E_{\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right) \sim p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)-\mathcal{H}\left(p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right)\right]
$$

Guided Policy Search, Levine and Colton 2013

- Act as randomly as possible while minimizing the cost! What does this remind us of?

## Which controller to collect samples with?

$$
\min \sum_{t=1}^{T} E_{\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right) \sim p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)-\mathcal{H}\left(p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right)\right]
$$

Guided Policy Search, Levine and Colton 2013

- Act as randomly as possible while minimizing the cost! What does this remind us of?
- MaxEntIOC: be as random as possible while matching the feature counts of demonstrated paths

$$
\begin{gathered}
\max _{P}-\sum_{\tau} P(\tau) \log P(\tau) \\
\sum_{\tau} P(\tau) f_{\tau}=f_{\mathrm{dem}}
\end{gathered}
$$

## Time varying linear dynamics

We iteratively fit dynamics and update the policy. Why such iteration is important?
So that the space (state, action distribution) our dynamics are estimated is similar to the one our policy visits (last lecture).

$$
\begin{aligned}
& p\left(\mathbf{x}_{t+1} \mid \mathbf{x}_{t}, \mathbf{u}_{t}\right)=\mathcal{N}\left(f\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right), \Sigma\right) \\
& f\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right) \approx \mathbf{A}_{t} \mathbf{x}_{t}+\mathbf{B}_{t} \mathbf{u}_{t} \\
& \mathbf{A}_{t}=\frac{d f}{d \mathbf{x}_{t}} \quad \mathbf{B}_{t}=\frac{d f}{d \mathbf{u}_{t}}
\end{aligned}
$$

## Fitting time varying linear dynamics

- Can we further improve sample complexity? Right now each sample ( $x_{t}, u_{t}, x_{t+1}$ ) contributes in one linear model fitting.
- Instead of linear regression use Bayesian linear regression!

$$
\begin{aligned}
& p\left(\mathbf{x}_{t+1} \mid \mathbf{x}_{t}, \mathbf{u}_{t}\right)=\mathcal{N}\left(f\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right), \Sigma\right) \\
& f\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right) \approx \mathbf{A}_{t} \mathbf{x}_{t}+\mathbf{B}_{t} \mathbf{u}_{t} \\
& \mathbf{A}_{t}=\frac{d f}{d \mathbf{x}_{t}} \quad \mathbf{B}_{t}=\frac{d f}{d \mathbf{u}_{t}}
\end{aligned}
$$

## Bayesian Linear regression

Let $\beta$ be the weights of our linear regression model:

$$
y=X \beta+\epsilon . \quad \epsilon_{i} \sim \mathrm{~N}\left(0, \sigma^{2}\right) . \quad \quad p\left(y \mid X, \beta ; \sigma^{2}\right)=\frac{1}{\left(2 \pi \sigma^{2}\right)^{n / 2}} \exp \left(-\frac{1}{2 \sigma^{2}}\|y-X \beta\|^{2}\right)
$$

## Bayesian Linear regression

Let $\beta$ be the weights of our linear regression model:

$$
y=X \beta+\epsilon . \quad \epsilon_{i} \sim \mathrm{~N}\left(0, \sigma^{2}\right) . \quad \quad p\left(y \mid X, \beta ; \sigma^{2}\right)=\frac{1}{\left(2 \pi \sigma^{2}\right)^{n / 2}} \exp \left(-\frac{1}{2 \sigma^{2}}\|y-X \beta\|^{2}\right)
$$

By maximizing the log likelihood we get the MLE solution for the weights:

$$
\hat{\beta}=\left(X^{T} X\right)^{-1} X^{T} y \quad \hat{\beta} \sim \mathrm{~N}\left(\beta, \sigma^{2}\left(X^{T} X\right)^{-1}\right)
$$

## Bayesian Linear regression

Let $\beta$ be the weights of our linear regression model:

$$
y=X \beta+\epsilon . \quad \epsilon_{i} \sim \mathrm{~N}\left(0, \sigma^{2}\right) . \quad \quad p\left(y \mid X, \beta ; \sigma^{2}\right)=\frac{1}{\left(2 \pi \sigma^{2}\right)^{n / 2}} \exp \left(-\frac{1}{2 \sigma^{2}}\|y-X \beta\|^{2}\right)
$$

By maximizing the log likelihood we get the MLE solution for the weights:

$$
\hat{\beta}=\left(X^{T} X\right)^{-1} X^{T} y \quad \hat{\beta} \sim \mathrm{~N}\left(\beta, \sigma^{2}\left(X^{T} X\right)^{-1}\right)
$$

What if we assume the following prior for the weights:

$$
\beta \sim N\left(0, \Lambda^{-1}\right)
$$

## Bayesian Linear regression

Let $\beta$ be the weights of our linear regression model:

$$
y=X \beta+\epsilon . \quad \epsilon_{i} \sim \mathrm{~N}\left(0, \sigma^{2}\right) . \quad \quad p\left(y \mid X, \beta ; \sigma^{2}\right)=\frac{1}{\left(2 \pi \sigma^{2}\right)^{n / 2}} \exp \left(-\frac{1}{2 \sigma^{2}}\|y-X \beta\|^{2}\right)
$$

By maximizing the log likelihood we get the MLE solution for the weights:

$$
\hat{\beta}=\left(X^{T} X\right)^{-1} X^{T} y \quad \hat{\beta} \sim \mathrm{~N}\left(\beta, \sigma^{2}\left(X^{T} X\right)^{-1}\right)
$$

What if we assume the following prior for the weights:

$$
\beta \sim \mathrm{N}\left(0, \Lambda^{-1}\right)
$$

Then the posterior will be:

$$
\begin{array}{ll}
P\left(\beta \mid y, X ; \sigma^{2}\right) \propto P\left(y \mid \beta ; \sigma^{2}\right) P(\beta) & \\
& \beta \sim \mathrm{N}\left(\mu_{n}, \Sigma_{n}\right), \\
p\left(\beta \mid y ; X, \sigma^{2}\right) \propto \exp \left(-\frac{1}{2 \sigma^{2}}\|y-X \beta\|^{2}-\frac{1}{2} \beta^{T} \Lambda \beta\right) & \mu_{n}=\left(X^{T} X+\sigma^{2} \Lambda\right)^{-1} X^{T} y, \\
\Sigma_{n}=\sigma^{2}\left(X^{T} X+\sigma^{2} \Lambda\right)^{-1} .
\end{array}
$$

## Bayesian Linear dynamics fitting

Fit a Global Gaussian Mixture Model using all samples ( $x_{t}, u_{t}, x_{t+1}$ ) of all iterations and time steps. -> prior
Use current samples (from this iteration) and obtain Gaussian posterior for ( $x_{t}, u_{t}, x_{t+1}$ ), which you condition to obtain $p\left(x_{t+1} \mid x_{t}, u_{t}\right)$.
Such prior results in 4 to 8 times less samples needed, despite the fact that it is not accurate enough by itself.

$$
\begin{aligned}
\Sigma & =\frac{\boldsymbol{\Phi}+N \hat{\Sigma}+\frac{N m}{N+m}\left(\hat{\mu}-\mu_{0}\right)\left(\hat{\mu}-\mu_{0}\right)^{\mathrm{T}}}{N+n_{0}} \\
\mu & =\frac{m \mu_{0}+n_{0} \hat{\mu}}{m+n_{0}} .
\end{aligned}
$$

Posterior of mean and covariance where $\hat{\mu}, \hat{\Sigma}$ are the empirical means and covariances and $\Phi, \mu_{0}, n_{0}, m$ an inverse Wishart prior

## Bayesian Linear dynamics fitting

Fit a Global Model of Dynamics by fitting a Neural Network using all samples $\left(x_{t}, u_{t}, x_{t+1}\right)$ of all iterations and time steps, and across multiple manipulation tasks->multi-task learning.
Use model predictive control with iLQR for computing the policy at every time step.
State is the robotic arm configuration and cost depends on a desired endeffector pose. No object involved in the state.

$$
\begin{aligned}
& \bar{f}([\mathbf{x} ; \mathbf{u}]) \approx \bar{f}\left(\left[\mathbf{x}_{i} ; \mathbf{u}_{i}\right]\right)+\frac{d \bar{f}}{d[\mathbf{x} ; \mathbf{u}]}^{\mathrm{T}}\left([\mathbf{x} ; \mathbf{u}]-\left[\mathbf{x}_{i} ; \mathbf{u}_{i}\right]\right) \\
& \bar{\mu}=\left[\begin{array}{c}
{\left[\mathbf{x}_{i} ; \mathbf{u}_{i}\right]} \\
\bar{f}\left(\left[\mathbf{x}_{i} ; \mathbf{u}_{i}\right]\right)
\end{array}\right] \\
& \bar{\Sigma}=\left[\begin{array}{cc}
\bar{\Sigma}_{\mathbf{x u}, \mathbf{x u}} & \frac{d \bar{f}}{}{ }^{\mathrm{T}} \bar{\Sigma}_{\mathbf{x u}, \mathbf{x u}} \\
\bar{\Sigma}_{\mathbf{x u}, \mathbf{x u}} \frac{d \bar{f}}{d[\mathbf{x} ; \mathbf{u}]} & \frac{d \bar{f}}{d[\mathbf{x} ; \mathbf{u}]} \mathrm{T} \mathrm{\Sigma}_{\mathbf{x u}, \mathbf{x u}} \frac{d \bar{f}}{d[\mathbf{x} ; \mathbf{u}]}+\bar{\Sigma}_{\mathbf{x}^{\prime}, \mathbf{x}^{\prime}}
\end{array}\right]
\end{aligned}
$$

## Step-size in iterative LQR

Remember from the last lecture:
The quadratic approximation in invalid too far away from the reference trajectory

$$
\hat{\mathbf{x}} \leftarrow \arg \min _{\mathbf{x}} \frac{1}{2}(\mathbf{x}-\hat{\mathbf{x}})^{T} \mathbf{H}(\mathbf{x}-\hat{\mathbf{x}})+\mathbf{g}^{T}(\mathbf{x}-\hat{\mathbf{x}})
$$

## Step-size in iterative LQR

Remember from the last lecture:
The quadratic approximation in invalid too far away from the reference trajectory

$$
\hat{\mathbf{x}} \leftarrow \arg \min _{\mathbf{x}} \frac{1}{2}(\mathbf{x}-\hat{\mathbf{x}})^{T} \mathbf{H}(\mathbf{x}-\hat{\mathbf{x}})+\mathbf{g}^{T}(\mathbf{x}-\hat{\mathbf{x}})
$$

Instead of using the argmin we do a line search:
$\rightarrow$ until convergence:

$$
\begin{aligned}
& \mathbf{F}_{t}=\nabla_{\mathbf{x}_{t}, \mathbf{u}_{t}} f\left(\hat{\mathbf{x}}_{t}, \hat{\mathbf{u}}_{t}\right) \\
& \mathbf{c}_{t}=\nabla_{\mathbf{x}_{t}, \mathbf{u}_{t}} c\left(\hat{\mathbf{x}}_{t}, \hat{\mathbf{u}}_{t}\right) \\
& \mathbf{C}_{t}=\nabla_{\mathbf{x}_{t}, \mathbf{u}_{t}}^{2} c\left(\hat{\mathbf{x}}_{t}, \hat{\mathbf{u}}_{t}\right)
\end{aligned}
$$

line search for $\alpha$

Run LQR backward pass on state $\delta \mathbf{x}_{t}=\mathbf{x}_{t}-\hat{\mathbf{x}}_{t}$ and action $\delta \mathbf{u}_{t}=\mathbf{u}_{t}-\hat{\mathbf{u}}_{t}$ Run forward pass with real nonlinear dynamics and $u_{t}=\hat{u}_{t}+K_{t}\left(x_{t}-\hat{x}_{T}\right)+\alpha k_{t}$

Update $\hat{\mathbf{x}}_{t}$ and $\hat{\mathbf{u}}_{t}$ based on states and actions in forward pass

## Step-size in iterative LQR

- Both the quadratic cost approximation and the fitted linear dynamics are invalid too far away from the reference trajectory.
- We want the trajectory distributions not to change much from iteration to iteration of our policy.
- Constraint the KL divergence between trajectory distributions:
$D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau)) \leq \epsilon$

$$
\begin{aligned}
& p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)=\mathcal{N}\left(\mathbf{K}_{t}\left(\mathbf{x}_{t}-\hat{\mathbf{x}}_{t}\right)+\mathbf{k}_{t}+\hat{\mathbf{u}}_{t}, \Sigma_{t}\right) \\
& p(\tau)=p\left(\mathbf{x}_{1}\right) \prod_{t=1}^{T} p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right) p\left(\mathbf{x}_{t+1} \mid \mathbf{x}_{t}, \mathbf{u}_{t}\right)
\end{aligned}
$$

## KL-divergences between trajectories

KL divergence between trajectory distributions translates to KL divergence between policies.

$$
\begin{aligned}
& D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau))=E_{p(\tau)}[\log p(\tau)-\log \bar{p}(\tau)] \\
& p(\tau)=p\left(\mathbf{x}_{1}\right) \prod_{t=1}^{T} p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right) p\left(\mathbf{x}_{t+1} \mid \mathbf{x}_{t}, \mathbf{u}_{t}\right) \quad \bar{p}(\tau)=\underline{\frac{p\left(\mathbf{x}_{1}\right)}{\text { dynamics \& initial state are the same! }} \prod_{t=1}^{T} \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right) p\left(\mathbf{x}_{t+1} \mid \mathbf{x}_{t}, \mathbf{u}_{t}\right)}
\end{aligned}
$$

## KL-divergences between trajectories

KL divergence between trajectory distributions translates to KL divergence between policies.

$$
\begin{aligned}
& D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau))=E_{p(\tau)}[\log p(\tau)-\log \bar{p}(\tau)] \\
& p(\tau)=p\left(\mathbf{x}_{1}\right) \prod_{t=1}^{T} p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right) p\left(\mathbf{x}_{t+1} \mid \mathbf{x}_{t}, \mathbf{u}_{t}\right) \quad \bar{p}(\tau)=\underline{p\left(\mathbf{x}_{1}\right)} \prod_{t=1}^{T} \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right) p\left(\mathbf{x}_{t+1} \mid \mathbf{x}_{t}, \mathbf{u}_{t}\right)
\end{aligned}
$$

$$
\log p(\tau)-\log \bar{p}(\tau)=\log p\left(x_{1}\right)+\sum_{t=1}^{T} \log p\left(u_{t} \mid x_{t}\right)+\log p\left(x_{t+1} \mid x_{t}, u_{t}\right)
$$

$$
-\log p\left(x_{1}\right)+\sum_{t=1}^{T}-\log \bar{p}\left(u_{t} \mid x_{t}\right)-\log p\left(x_{t+1} \mid x_{t}, u_{t}\right)
$$

## KL-divergences between trajectories

KL divergence between trajectory distributions translates to KL divergence between policies.

$$
\begin{aligned}
& D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau))=E_{p(\tau)}[\log p(\tau)-\log \bar{p}(\tau)] \\
& p(\tau)=p\left(\mathbf{x}_{1}\right) \prod_{t=1}^{T} p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right) p\left(\mathbf{x}_{t+1} \mid \mathbf{x}_{t}, \mathbf{u}_{t}\right) \quad \bar{p}(\tau)=\underbrace{p\left(\mathbf{x}_{1}\right)}_{\text {dynamics \& initial state are the same! }} \prod_{t=1}^{T} \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right) \underline{p\left(\mathbf{x}_{t+1} \mid \mathbf{x}_{t}, \mathbf{u}_{t}\right)} \\
& \begin{aligned}
\log p(\tau)-\log \bar{p}(\tau)= & \log p\left(x_{1}\right)+\sum_{t=1}^{T} \log p\left(u_{t} \mid x_{t}\right)+\log p\left(x_{t+1} \mid x_{t}, u_{t}\right)
\end{aligned} \\
& \quad-\log p\left(x_{1}\right)+\sum_{t=1}^{T}-\log \bar{p}\left(u_{t} \mid x_{t}\right)-\log p\left(x_{t+1} \mid x_{t}, u_{t}\right) \\
& D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau))=E_{p(\tau)}\left[\sum_{t=1}^{T} \log p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)-\log \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right]
\end{aligned}
$$

## KL-divergences between trajectories

KL divergence between trajectory distributions translates to KL divergence between policies.
KL divergence constraints are important to ensure monotonic improvement of the policy behavior also in model-free environments.

Covariant policy search (Bagnell et all), Natural policy gradient (Kakade 2001), Relative entropy policy search (Peters et al. 2003), utilize such constraints when taking the policy gradient.
Theoretical guarantees for a general policy parametrization and a practical algorithm were given recently in the TRPO Schulman et al.

## Trust Region Policy Optimization

## Police gradients with monotonic guarantees!

- Police gradients: have a function approximation for the policy $\pi_{\theta}(u \mid x)$ and optimize use SGD. SGD is sufficient to learn great object object detectors for example. What is different in RL?
- Non-stationarity in RL: Each time the policy changes the state visitation distribution changes. And this can cause the policy to diverge!
- Contribution: theoretical and practical method of how big of a step our gradient can take.

## Problem Setup

Problem: minimize expected cost of policy

$$
\begin{aligned}
& \eta(\pi)=\mathbb{E}_{s_{0}, a_{0}, \ldots}\left[\sum_{t=0}^{\infty} \gamma^{t} c\left(s_{t}\right), \text { where }\right] \\
& s_{0} \sim \rho_{0}\left(s_{0}\right), a_{t} \sim \pi\left(a_{t} \mid s_{t}\right), s_{t+1} \sim P\left(s_{t+1} \mid s_{t}, a_{t}\right)
\end{aligned}
$$

- Suppose we execute policy $\pi$ in the MDP, obtaining a set of trajectories.
- Using these trajectories, can we construct loss function $L$ that is a local approximation for the expected cost $\eta$ ?

## A Neat Identity

Advantage function: $A_{\pi}(s, a)=Q_{\pi}(s, a)-V_{\pi}(s)$
Visitation distribution: $\rho_{\pi}(s)=\left(P\left(s_{0}=s\right)+\gamma P\left(s_{1}=s\right)+\gamma^{2} P\left(s_{2}=s\right)+\ldots\right)$

Expected cost of new policy can be written in terms of old one

$$
\eta(\tilde{\pi})=\eta(\pi)+\sum_{s} \rho_{\tilde{\pi}}(s) \sum_{a} \tilde{\pi}(a \mid s) A_{\pi}(s, a)
$$

## Surrogate Loss Function

$\eta(\tilde{\pi})$ has complicated dependence on $\tilde{\pi}$ through $\rho_{\tilde{\pi}}(s)$
Define surrogate loss L, a local approximation to $\eta$

$$
\begin{aligned}
& \eta(\tilde{\pi})=\eta(\pi)+\sum_{s} \rho_{\tilde{\pi}}(s) \sum_{a} \tilde{\pi}(a \mid s) A_{\pi}(s, a) \\
& L_{\pi}(\tilde{\pi})=\eta(\pi)+\sum_{s} \rho_{\pi}(s) \sum_{a} \tilde{\pi}(a \mid s) A_{\pi}(s, a)
\end{aligned}
$$

## Improvement Theorem

$$
\begin{gathered}
\eta(\tilde{\pi}) \leq L_{\pi}(\tilde{\pi})+C D_{\mathrm{KL}}^{\max }(\pi, \tilde{\pi}), \text { where } C=\frac{2 \epsilon \gamma}{(1-\gamma)^{2}} \\
\epsilon=\max _{s}\left|\mathbb{E}_{a \sim \pi^{\prime}(a \mid s)}\left[A_{\pi}(s, a)\right]\right| \\
D_{\mathrm{KL}}^{\max }(\pi, \tilde{\pi})=\max _{s} D_{\mathrm{KL}}(\pi(\cdot \mid s) \| \tilde{\pi}(\cdot \mid s))
\end{gathered}
$$

Mixture policy update considered by Kakade and Langford:

$$
\pi_{\text {new }}(a \mid s)=(1-\alpha) \pi_{\text {old }}(a \mid s)+\alpha \pi^{\prime}(a \mid s) .
$$

## Algorithm

- Optimize surrogate loss + KL penalty => guaranteed improvement to $\eta$

## Review

- Devised a surrogate loss L, which is a tractable local approximation to $\eta$

$$
L_{\pi}(\tilde{\pi})=\eta(\pi)+\sum_{s} \rho_{\pi}(s) \sum_{a} \tilde{\pi}(a \mid s) A_{\pi}(s, a)
$$

- KL-penalized surrogate loss majorities the true objective $\eta$

$$
\eta(\tilde{\pi}) \leq L_{\pi}(\tilde{\pi})+C D_{\mathrm{KL}}^{\max }(\pi, \tilde{\pi}), \text { where } C=\frac{2 \epsilon \gamma}{(1-\gamma)^{2}}
$$

- We don't have an algorithm yet: need to construct $L_{\pi}$ from sampled data, and make approximations

## Sampling

$$
L_{\pi}(\tilde{\pi})=\eta(\pi)+\sum_{s} \rho_{\pi}(s) \sum_{a} \tilde{\pi}(a \mid s) A_{\pi}(s, a)
$$

- Want to construct an objective that in expectation equals $L$ plus a constant independent of $\tilde{\pi}$
- Execute policy to sample states from $\rho_{\pi}$
- Use empirical returns in place of $A_{\pi}$

## Approximations

## Relation to Policy Iteration and Natural Policy Gradient

Trust region policy optimization:

$$
\begin{aligned}
& \underset{\theta}{\operatorname{minimize}} L_{\theta_{\text {old }}}(\theta) \\
& \text { subject to } \bar{D}_{\mathrm{KL}}^{\rho_{\theta_{\text {old }}}}\left(\theta_{\text {old }}, \theta\right) \leq \delta
\end{aligned}
$$

## Natural Policy Gradient:

TRPO in limit as $\delta \rightarrow 0$

Policy Gradient:

$$
\begin{aligned}
& \underset{\theta}{\operatorname{minimize}}\left[\left.\nabla_{\theta} L_{\theta_{\text {old }}}(\theta)\right|_{\theta=\theta_{\text {old }}} \cdot\left(\theta-\theta_{\text {old }}\right)\right] \\
& \text { subject to } \frac{1}{2}\left\|\theta-\theta_{\text {old }}\right\|^{2} \leq \delta .
\end{aligned}
$$

Relative entropy policy search (Peters et al. 2010) constraints the state-action marginals p(a,s) instead of $p$ (als)

- How to solve this constrained optimization problem at every iteration?
- Authors used a direction search based on quadratic approximation of the constraint and then line search to find the step so that constraint is not violated and the surrogate cost goes down.

## Experiments: Simulated Robot Control

Policy parametrization as a neural network

Cost function: move forward and don't fall over

## Constraint Optimization in iLQR

$$
\min _{p} \sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)\right] \text { s.t. } D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau)) \leq \epsilon
$$

KL-divergences between trajectories:

$$
\begin{aligned}
& D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau))=\sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[\log p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)-\log \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right] \\
& D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau))=\sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[-\log \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right]+E_{p\left(\mathbf{x}_{t}\right)}[\underbrace{\left.E_{p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)}\left[\log p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right]\right]} \\
& D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau))=\sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[-\log \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)-\mathcal{H}\left(p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right)\right]
\end{aligned}
$$

## KL-divergences between trajectories

We have the following constrained optimization problem:

$$
\begin{aligned}
& \min _{p} \sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)\right] \text { s.t. } D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau)) \leq \epsilon \\
& D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau))=\sum_{t=1}^{T} E_{p\left(x_{t}, u_{t}\right)}-\left[\log \bar{p}\left(u_{t} \mid x_{t}\right)-\mathcal{H}\left(p\left(u_{t} \mid x_{t}\right)\right)\right]
\end{aligned}
$$

Reminder: Linear-Gaussian solves $\min \sum_{t=1}^{T} E_{p\left(x_{t}, u_{t}\right)}\left[c\left(x_{t}, u_{t}\right)-\mathcal{H}\left(p\left(u_{t} \mid x_{t}\right)\right)\right]$
$p\left(u_{t} \mid x_{t}\right)=\mathcal{N}\left(K_{t}\left(x_{t}-\hat{x}_{t}\right)+k_{t}+\hat{u}_{t}, \Sigma_{t}\right)$
If we can get $D_{\mathrm{KL}}$ into the cost, we can just use iLQR!

## We will solve it with dual gradient descent

$$
\min _{\mathbf{x}} f(\mathbf{x}) \text { s.t. } C(\mathbf{x})=0
$$

$\mathcal{L}(\mathbf{x}, \lambda)=f(\mathbf{x})+\lambda C(\mathbf{x})$
$g(\lambda)=\inf _{\mathbf{x}} \mathcal{L}(\mathbf{x}, \lambda)$
$\lambda \leftarrow \arg \max _{\lambda} g(\lambda)$

How to maximize? Compute gradients!

## Digression: dual gradient descent

$$
\begin{aligned}
& \min _{\mathbf{x}} f(\mathbf{x}) \text { s.t. } C(\mathbf{x})=0 \quad \mathcal{L}(\mathbf{x}, \lambda)=f(\mathbf{x})+\lambda C(\mathbf{x}) \\
& g(\lambda)=\inf _{\mathbf{x}} \mathcal{L}(\mathbf{x}, \lambda) \\
& g(\lambda)=\mathcal{L}\left(\mathbf{x}^{\star}(\lambda), \lambda\right) \\
& \frac{d g}{d \lambda}=\frac{d \mathcal{L}}{d \mathbf{x}^{\star}} \frac{d \mathbf{x}^{\star}}{d \lambda}+\frac{d \mathcal{L}}{d \lambda} \quad \text { if } \mathbf{x}^{\star}=\arg \min _{\mathbf{x}} \mathcal{L}(\mathbf{x}, \lambda), \text { then } \frac{d \mathcal{L}}{d \mathbf{x}^{\star}}=0!
\end{aligned}
$$

## Digression: dual gradient descent

$$
\begin{array}{ll}
\min _{\mathbf{x}} f(\mathbf{x}) \text { s.t. } C(\mathbf{x})=0 & \mathcal{L}(\mathbf{x}, \lambda)=f(\mathbf{x})+\lambda C(\mathbf{x}) \\
g(\lambda)=\mathcal{L}\left(\mathbf{x}^{\star}(\lambda), \lambda\right) & 1 . \text { Find } \mathbf{x}^{\star} \leftarrow \arg \min _{\mathbf{x}} \mathcal{L}(\mathbf{x}, \lambda) \\
\mathbf{x}^{\star}=\arg \min _{\mathbf{x}} \mathcal{L}(\mathbf{x}, \lambda) & 2 . \text { Compute } \frac{d g}{d \lambda}=\frac{d \mathcal{L}}{d \lambda}\left(\mathbf{x}^{\star}, \lambda\right) \\
\frac{d g}{d \lambda}=\frac{d \mathcal{L}}{d \lambda}\left(\mathbf{x}^{\star}, \lambda\right) & 3 . \lambda \leftarrow \lambda+\alpha \frac{d g}{d \lambda}
\end{array}
$$

## DGD with iterative LQR

This is the constrained problem we want to solve:

$$
\begin{aligned}
& \min _{p} \sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)\right] \text { s.t. } D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau)) \leq \epsilon \\
& D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau))=\sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[-\log \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)-\mathcal{H}\left(p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right)\right] \\
& \mathcal{L}(p, \lambda)=\sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)-\lambda \log \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)-\lambda \mathcal{H}\left(p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right)\right]-\lambda \epsilon
\end{aligned}
$$

## DGD with iterative LQR

$$
\begin{aligned}
& \min _{p} \sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)\right] \text { s.t. } D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau)) \leq \epsilon \\
& \mathcal{L}(p, \lambda)=\sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)-\lambda \log \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)-\lambda \mathcal{H}\left(p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right)\right]-\lambda \epsilon
\end{aligned}
$$

1. Find $p^{*} \leftarrow \arg \min _{p} \mathcal{L}(p, \lambda)$
2. Compute $\frac{d g}{d \lambda}=\frac{d \mathcal{L}}{d \lambda}\left(p^{*}, \lambda\right)$
3. $\lambda \leftarrow \lambda+\alpha \frac{d g}{d \lambda}$

## DGD with iterative LQR

1. Find $p^{\star} \leftarrow \arg \min _{p} \mathcal{L}(p, \lambda)$
$\min _{p} \sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)-\lambda \log \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)-\lambda \mathcal{H}\left(p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right)\right]-\lambda \epsilon$
Reminder: Linear-Gaussian solves $\min \sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)-\mathcal{H}\left(p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right)\right]$
$p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)=\mathcal{N}\left(\mathbf{K}_{t}\left(\mathbf{x}_{t}-\hat{\mathbf{x}}_{t}\right)+\mathbf{k}_{t}+\hat{\mathbf{u}}_{t}, \Sigma_{t}\right)$
$\min _{p} \sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[\frac{1}{\lambda} c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)-\log \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)-\mathcal{H}\left(p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)\right)\right]$
Just use LQR with cost $\tilde{c}\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)=\frac{1}{\lambda} c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)-\log \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)$

## DGD with iterative LQR

$$
\min _{p} \sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)\right] \text { s.t. } D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau)) \leq \epsilon
$$

1. Set $\tilde{c}\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)=\frac{1}{\lambda} c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)-\log \bar{p}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)$
2. Use LQR to find $p^{\star}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)$ using $\tilde{c}$
3. $\lambda \leftarrow \lambda+\alpha\left(D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau))-\epsilon\right)$

- Learning local linear dynamics models
- Using KL divergence constraints for global and local policy search

## Learning general policies by imitating local controllers

- Each iLQR controller achieves the task from a specific initial state x_0
- We want to learn general policies by mimicking such controllers. Why?
- This policy will succeed under different forms of initial conditions. We hope with optimal controllers in the loop to do better than simple trial and error and require less human demonstrations than imitating human experts directly. However, ti will require measuring the cost at training time.
- Those general policies can be: a non parametric nearest neighbor local controller selection or a neural network policy $\pi_{\theta}(x)$

## Imitating local controllers with DAGGER

Dataset AGGregation: bring learner's and expert's trajectory distributions closer by labelling additional data points resulting from applying the current policy

1. train $\pi_{\theta}\left(u_{t} \mid o_{t}\right)$ from human data $\mathcal{D}_{\pi^{*}}=\left\{o_{1}, u_{1}, \ldots, o_{N}, u_{N}\right\}$
2. run $\pi_{\theta}\left(u_{t} \mid o_{t}\right)$ to get dataset $\mathcal{D}_{\pi}=\left\{o_{1}, \ldots, o_{M}\right\}$
3. Ask human to label $\mathcal{D}_{\pi}$ with actions $u_{t}$
4. Aggregate: $\mathcal{D}_{\pi^{*}} \leftarrow \mathcal{D}_{\pi^{*}} \cup \mathcal{D}_{\pi}$
5. GOTO step 1.

Execute current policy and Query Expert

## Imitating local controllers with DAGGER

Dataset AGGregation: bring learner's and expert's trajectory distributions closer by labelling additional data points resulting from applying the current policy

1. train $\pi_{\theta}\left(u_{t} \mid o_{t}\right)$ from human data $\mathcal{D}_{\pi^{*}}=\left\{o_{1}, u_{1}, \ldots, o_{N}, u_{N}\right\}$
2. run $\pi_{\theta}\left(u_{t} \mid o_{t}\right)$ to get dataset $\mathcal{D}_{\pi}=\left\{o_{1}, \ldots, o_{M}\right\}$
3. Ask human to label $\mathcal{D}_{\pi}$ with actions $u_{t}$
4. Aggregate: $\mathcal{D}_{\pi^{*}} \leftarrow \mathcal{D}_{\pi^{*}} \cup \mathcal{D}_{\pi}$
5. GOTO step 1.

- repeatedly query the expert

## Imitating local controllers with DAGGER

Dataset AGGregation: bring learner's and expert's trajectory distributions closer by labelling additional data points resulting from applying the current policy

1. train $\pi_{\theta}\left(u_{t} \mid o_{t}\right)$ from controller data $\mathcal{D}_{\pi^{*}}=\left\{o_{1}, u_{1}, \ldots, o_{N}, u_{N}\right\}$
2. run $\pi_{\theta}\left(u_{t} \mid o_{t}\right)$ to get dataset $\mathcal{D}_{\pi}=\left\{o_{1}, \ldots, o_{M}\right\}$
3. Ask controller to label $\mathcal{D}_{\pi}$ with actions $u_{t}$
4. Aggregate: $\mathcal{D}_{\pi^{*}} \leftarrow \mathcal{D}_{\pi^{*}} \cup \mathcal{D}_{\pi}$
5. GOTO step 1.

- repeatedly query the expert

## Imitating local controllers with DAGGER

Dataset AGGregation: bring learner's and expert's trajectory distributions closer by labelling additional data points resulting from applying the current policy

1. train $\pi_{\theta}\left(u_{t} \mid o_{t}\right)$ from controller data $\mathcal{D}_{\pi^{*}}=\left\{o_{1}, u_{1}, \ldots, o_{N}, u_{N}\right\}$
2. 

run $\pi_{\theta}\left(u_{t} \mid o_{t}\right)$ to get dataset $\mathcal{D}_{\pi}=\left\{o_{1}, \ldots, o_{M}\right\}$
3. Ask controller to label $\mathcal{D}_{\pi}$ with actions $u_{t}$
4. Aggregate: $\mathcal{D}_{\pi^{*}} \leftarrow \mathcal{D}_{\pi^{*}} \cup \mathcal{D}_{\pi}$
5. GOTO step 1.

- execute an unsafe/partially trained policy

- repeatedly query the expert

## DAGGER

- DAGGER assumes that the learner can imitate the expert. The expert comes close to the learner by matching the state distributions.
- Guided policy search does not require to execute a partially trained policy on hardware. The teacher further adapts to actions the learner can imitate.

## Guided Policy Search

- Impose constraints on trajectory optimization:
$\min _{\mathbf{u}_{1}, \ldots, \mathbf{u}_{T}, \mathbf{x}_{1}, \ldots, \mathbf{x}_{T}, \theta} \sum_{t=1}^{T} c\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)$ s.t. $\mathbf{x}_{t}=f\left(\mathbf{x}_{t-1}, \mathbf{u}_{t-1}\right) \quad \begin{aligned} & \text { generic trajectory } \\ & \text { optimization, solve } \\ & \text { however you want }\end{aligned}$
s.t. $\mathbf{u}_{t}=\pi_{\theta}\left(\mathbf{x}_{t}\right)$

## Solve it using dual gradient descent

$$
\begin{array}{ll}
\min _{\mathbf{x}} f(\mathbf{x}) \text { s.t. } C(\mathbf{x})=0 & \mathcal{L}(\mathbf{x}, \lambda)=f(\mathbf{x})+\lambda C(\mathbf{x}) \\
g(\lambda)=\mathcal{L}\left(\mathbf{x}^{\star}(\lambda), \lambda\right) & 1 . \text { Find } \mathbf{x}^{\star} \leftarrow \arg \min _{\mathbf{x}} \mathcal{L}(\mathbf{x}, \lambda) \\
\mathbf{x}^{\star}=\arg \min _{\mathbf{x}} \mathcal{L}(\mathbf{x}, \lambda) & 2 . \text { Compute } \frac{d g}{d \lambda}=\frac{d \mathcal{L}}{d \lambda}\left(\mathbf{x}^{\star}, \lambda\right) \\
\frac{d g}{d \lambda}=\frac{d \mathcal{L}}{d \lambda}\left(\mathbf{x}^{\star}, \lambda\right) & 3 . \lambda \leftarrow \lambda+\alpha \frac{d g}{d \lambda}
\end{array}
$$

## A small tweak to DGD: augmented Lagrangian

$$
\begin{array}{ll}
\min _{\mathbf{x}} f(\mathbf{x}) \text { s.t. } C(\mathbf{x})=0 & \mathcal{L}(\mathbf{x}, \lambda)=f(\mathbf{x})+\lambda C(\mathbf{x}) \\
& \overline{\mathcal{L}}(\mathbf{x}, \lambda)=f(\mathbf{x})+\lambda C(\mathbf{x})+\rho\|C(\mathbf{x})\|^{2}
\end{array}
$$ solution

- When far from solution, quadratic term tends to improve stability
- Closely related to alternating direction method of multipliers (ADMM) descent

$$
\min _{\tau, \theta} c(\tau) \text { s.t. } \mathbf{u}_{t}=\pi_{\theta}\left(\mathbf{x}_{t}\right)
$$

Lagrangian:

$$
\mathcal{L}(\tau, \theta, \lambda)=c(\tau)+\sum_{t=1}^{T} \lambda_{t}\left(\pi_{\theta}\left(\mathbf{x}_{t}\right)-\mathbf{u}_{t}\right)
$$

Augmented Lagrangian:
$\overline{\mathcal{L}}(\tau, \theta, \lambda)=c(\tau)+\sum_{t=1}^{T} \lambda_{t}\left(\pi_{\theta}\left(\mathbf{x}_{t}\right)-\mathbf{u}_{t}\right)+\sum_{t=1}^{T} \rho_{t}\left(\pi_{\theta}\left(\mathbf{x}_{t}\right)-\mathbf{u}_{t}\right)^{2}$

## Stochastic (Gaussian) GPS

$$
\begin{aligned}
& \min _{p, \theta} E_{\tau \sim p(\tau)}[c(\tau)] \text { s.t. } p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)=\pi_{\theta}\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right) \\
& p\left(\mathbf{u}_{t} \mid \mathbf{x}_{t}\right)=\mathcal{N}\left(\mathbf{K}_{t}\left(\mathbf{x}_{t}-\hat{\mathbf{x}}_{t}\right)+\mathbf{k}_{t}+\hat{\mathbf{u}}_{t}, \Sigma_{t}\right) \\
& \min _{p} \sum_{t=1}^{T} E_{p\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)}\left[\tilde{c}\left(\mathbf{x}_{t}, \mathbf{u}_{t}\right)\right] \text { s.t. } D_{\mathrm{KL}}(p(\tau) \| \bar{p}(\tau)) \leq \epsilon
\end{aligned}
$$

1. Optimize $p(\tau)$ with respect to some surrogate $\tilde{c}\left(x_{t}, u_{t}\right)$
2. Optimize $\theta$ with respect to some supervised objective
3. Increment or modify dual variables $\lambda$

## GPS with dual gradient descent

$$
\begin{aligned}
& \min _{\tau, \theta} c(\tau) \text { s.t. } \mathbf{u}_{t}=\pi_{\theta}\left(\mathbf{x}_{t}\right) \\
& \overline{\mathcal{L}}(\tau, \theta, \lambda)=c(\tau)+\sum_{t=1}^{T} \lambda_{t}\left(\pi_{\theta}\left(\mathbf{x}_{t}\right)-\mathbf{u}_{t}\right)+\sum_{t=1}^{T} \rho_{t}\left(\pi_{\theta}\left(\mathbf{x}_{t}\right)-\mathbf{u}_{t}\right)^{2}
\end{aligned}
$$

1. Find $\tau \leftarrow \arg \min _{\tau} \overline{\mathcal{L}}(\tau, \theta, \lambda)$ (e.g. via iLQR)
2. Find $\theta \leftarrow \arg \min _{\theta} \overline{\mathcal{L}}(\tau, \theta, \lambda)$ (e.g. via SGD)
3. $\lambda \leftarrow \lambda+\alpha \frac{d g}{d \lambda}$

## Guided policy search

## Guided policy search

> 1. Find $\tau \leftarrow \arg \min _{\tau} \overline{\mathcal{L}}(\tau, \theta, \lambda)$ (e.g. via iLQR)
> 2. Find $\theta \leftarrow \arg \min _{\theta} \overline{\mathcal{L}}(\tau, \theta, \lambda)$ (e.g. via SGD)
> 3. $\lambda \leftarrow \lambda+\alpha \frac{d g}{d \lambda}$

- Can be interpreted as constrained trajectory optimization method
- Can be interpreted as imitation of an optimal control expert, since step 2 is just supervised learning
- The optimal control "teacher" adapts to the learner, and avoids actions that the learner can't mimic

## DAGGER vs. GPS

- Dagger does not require an adaptive expert
- Any expert will do, so long as states from learned policy can be labeled
- Assumes it is possible to match expert's behavior up to bounded loss
- Not always possible (e.g. partially observed domains)
- GPS adapts the "expert" behavior
- Does not require bounded loss on initial expert (expert will change)
- It does require initial state resets!

## Imitating MPC: PLATO algorithm

1. Train $\pi_{\theta}\left(u_{t} \mid o_{t}\right)$ from controller data $\mathcal{D}=\left\{o_{1}, u_{1}, \ldots, o_{N}, u_{N}\right\}$
2. Run $\hat{\pi}\left(u_{t} \mid o_{t}\right)$ to get dataset $\mathcal{D}_{\pi}=\left\{o_{1}, \ldots, o_{M}\right\}$
3. Ask computer to label $\mathcal{D}_{\pi}$ with actions $u_{t}$
4. Aggregate: $\mathcal{D} \leftarrow \mathcal{D} \cup \mathcal{D}_{\pi}$
simple stochastic policy: $\hat{\pi}\left(u_{t} \mid x_{t}\right)=\mathcal{N}\left(K_{t} x_{t}+k_{t}, \Sigma_{u_{t}}\right)$

$$
\hat{\pi}\left(u_{t} \mid x_{t}\right)=\arg \min _{\hat{\pi}} \sum_{t^{\prime}=t}^{T} E_{\hat{\pi}}\left[c\left(x_{t^{\prime}}, u_{t^{\prime}}\right)\right]+\lambda D_{\mathrm{KL}}\left(\hat{\pi}\left(u_{t} \mid x_{t}\right) \| \pi_{\theta}\left(u_{t} \mid o_{t}\right)\right)
$$

## Imitating MPC: PLATO algorithm

simple stochastic policy: $\hat{\pi}\left(u_{t} \mid x_{t}\right)=\mathcal{N}\left(K_{t} x_{t}+k_{t}, \Sigma_{u_{t}}\right)$
$\hat{\pi}\left(u_{t} \mid x_{t}\right)=\arg \min _{\hat{\pi}} \sum_{t^{\prime}=t}^{T} E_{\hat{\pi}}\left[c\left(x_{t^{\prime}}, u_{t^{\prime}}\right)\right]+\lambda D_{\mathrm{KL}}\left(\hat{\pi}\left(u_{t} \mid x_{t}\right) \| \pi_{\theta}\left(u_{t} \mid o_{t}\right)\right)$
$\pi_{\theta}\left(u_{t} \mid o_{t}\right)$ Learner: trained from observations!
$\stackrel{\pi}{*}^{\star}\left(u_{t} \mid x_{t}\right)=\arg \min _{\hat{\pi}} \sum_{t^{\prime}=t}^{T} E_{\hat{\pi}}\left[c\left(x_{t^{\prime}}, u_{t^{\prime}}\right)\right]$

Replanning $=$ Model Predictive Control (MPC)
$\pi_{\theta}\left(u_{t} \mid o_{t}\right)$ - control from images
$\hat{\pi}\left(u_{t} \mid x_{t}\right)$ - control from states

## Observability at train and test time

$$
\min _{p, \theta} E_{\tau \sim p(\tau)}[c(\tau)] \text { s.t. } p\left(u_{t} \mid x_{t}\right)=\pi_{\theta}\left(u_{t} \mid o_{t}\right)
$$

test time

## Example: End-to-End training of Deep Visuomotor Policies

- Learning Neural Network general policies using direct RGB (no object detector, pose estimator or trackers) as input and trajectory optimization as supervision
- State: positions and velocities of joints, not object pose.
- Tasks: Swimmer, octopus etc, and peg insertion into a hole
- The RGB input is transformed to a set of $x, y$ key points at the final layer to avoid overfitting
- Pretraining of the video CNN using object pose regression
- The environment is fully observable at training time (e.g., objects at known positions so that we know the desired state of the robotic arm), but not at test time
- Train and test environments are overall similar, due to the small amount of training data that can be collected in real world with instrumented training scenarios

## Example: End-to-End training of Deep Visuomotor Policies

Example: End-to-End training of Deep Visuomotor Policies

## End-to-End Training of Deep Visuomotor Policies Learned Visual Representations

## Example: Learning Dexterous Manipulation Policies from Experience and Imitation

- Learning Neural Network and nearest neighbor based general policies using pose state as input and trajectory optimization as supervision
- State: positions and velocities of joints and objects—optitrack motion capture is used for object tracking at training time, and at test time for NNeib policy
- Tasks: dexterous manipulation, hard because of contact!
- iLQR fails without initialization from a demonstration!
- Nearest Neighbor using the object pose to determine which local policy to follow-requires saving all local controllers and knowing object pose (for effective matching)
- Neural net: can learn a mapping directly from on board sensing to actions, no vision, using GPS

## Example: Learning Dexterous Manipulation Policies from Experience and Imitation

## Learning Dexterous Manipulation Policies from Experience and Imitation

Vikash Kumar*, Abhishek Gupta^, Emanuel Todorov*, Sergey Livine^<br>*University of Washington, Seattle ^University of California, Berkeley

International Journal of Robotics Research

## Embed to Control: A Locally Linear latent Dynamics mode for Control from raw Images

- Infer a low-dimensional latent state space in which optimal control (LQR) can be used.
- Latent state should: 1) reconstruct the input image 2) predict the next state and then next observation 3) prediction should be locally linearizable

## Embed to Control: A Locally Linear latent Dynamics model for Control from raw Images

## Embed to Control

A Locally Linear Latent Dynamics Model for Control from Raw Images

Manuel Watter, Jost Tobias Springenberg, Joschka Boedecker, ${ }^{\star}$ Martin Riedmiller ${ }^{\dagger}$

- University of Freiburg, Machine Learning Lab $\dagger$ Google DeepMind

## Summary

- Learning local dynamics models
- i-LQR with learn local models
- Trust region constraint for policy optimization: TRPO and i-LQR
- Learning general policies by imitating i-LQR local controllers
- DAGGER
- Guided policy search

## Next lecture

- Differentiable model-based reinforcement learning
- Recurrent networks and optimal control
- Back-propagate directly to the policy using temporal unfoldingdifferentiable dynamics- back propagate through discrete actions (stochastic sampling on the forward pass), or through continuous actions (re-paramertization trick)
